

100% Autonomous Software Procurement

Deconstructing an AI agent's successful execution
of the Agentic Commerce Protocol (ACP).

Execution Date: 2026-06-01 | **Environment:** ods-qa | **Engine:** GLM-5.1

The machine began with a domain and a target, but no map.

Constraints

No browser UI

No human-in-the-loop

No API documentation

Starting Parameters

Target Domain

`https://ods-qa.openlinksw.com`

Objective Item

`Test File Access license (1 Year, $9.99)`

Authorisation

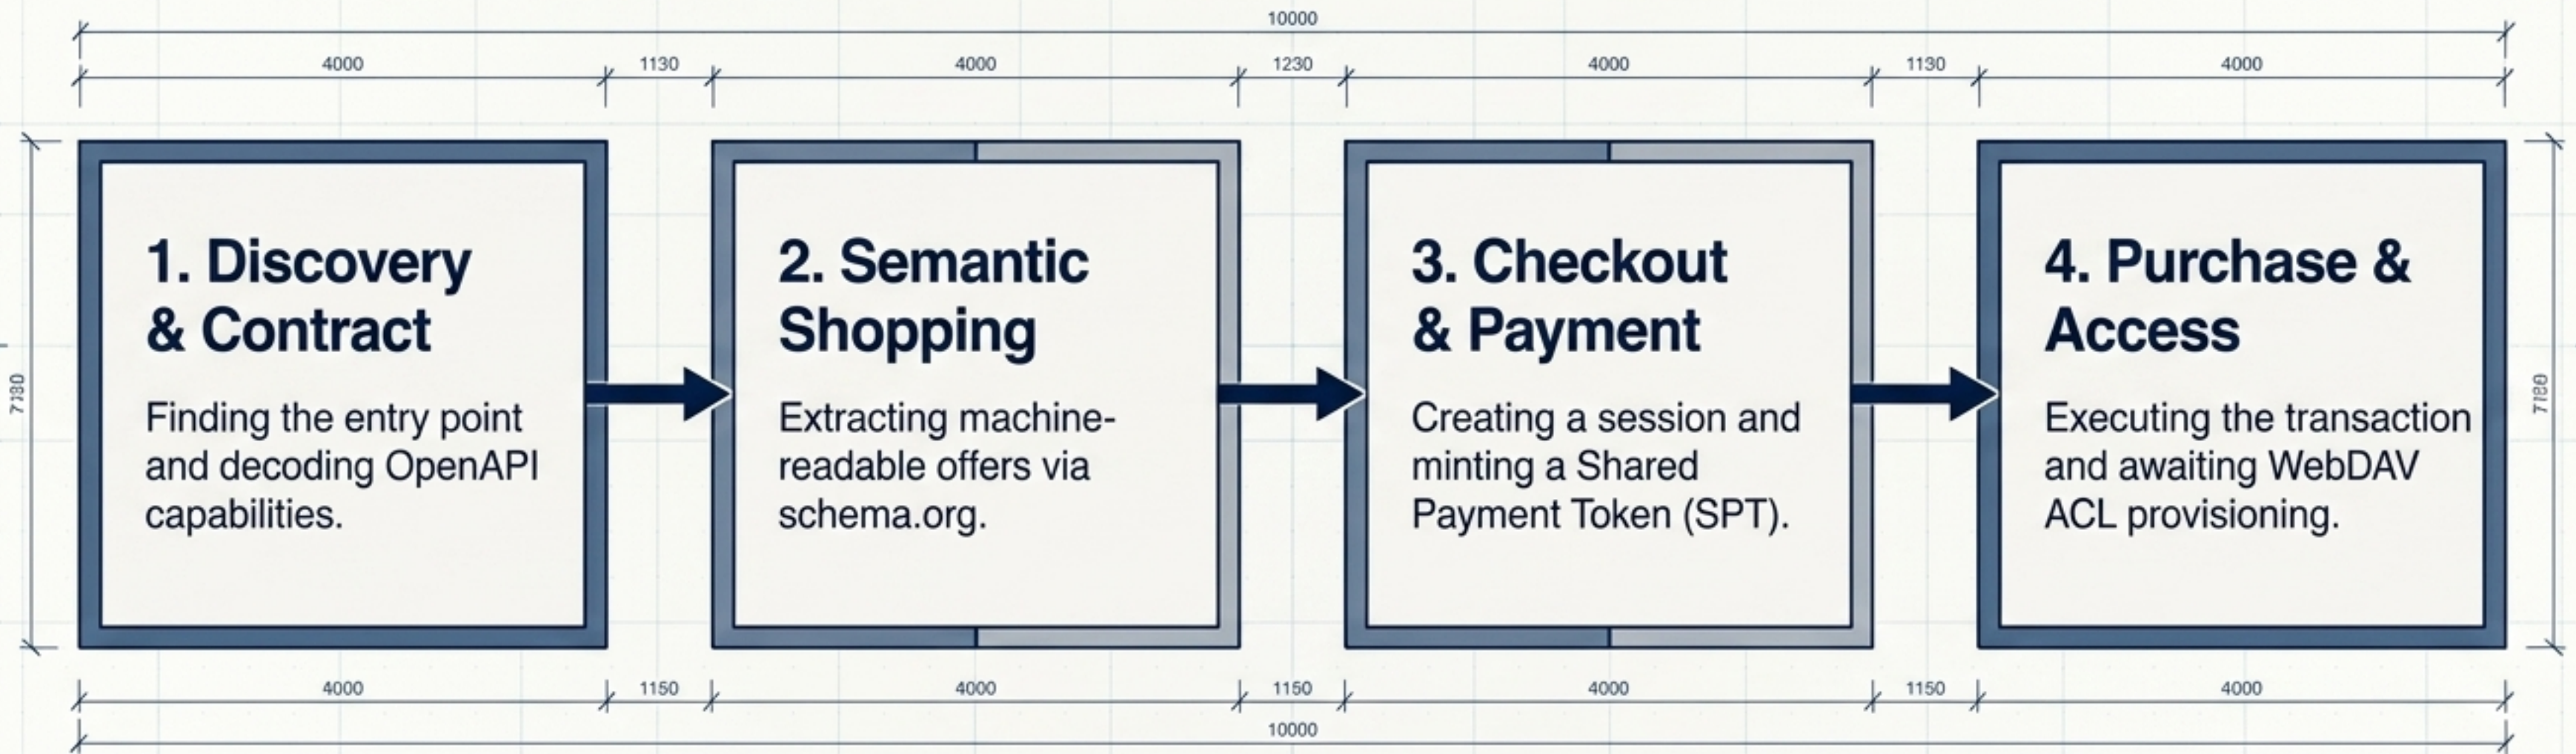

`Bearer Token [REDACTED]`

Payment Rail

`Stripe Test Key sk_test_...`

The core constraint: The agent must discover the endpoint, learn the contract, parse semantic offers, and pay via tokenised credentials entirely autonomously.

The Agentic Commerce Protocol (ACP) Execution Arc

Endpoint autodiscovery starts at the .well-known boundary.

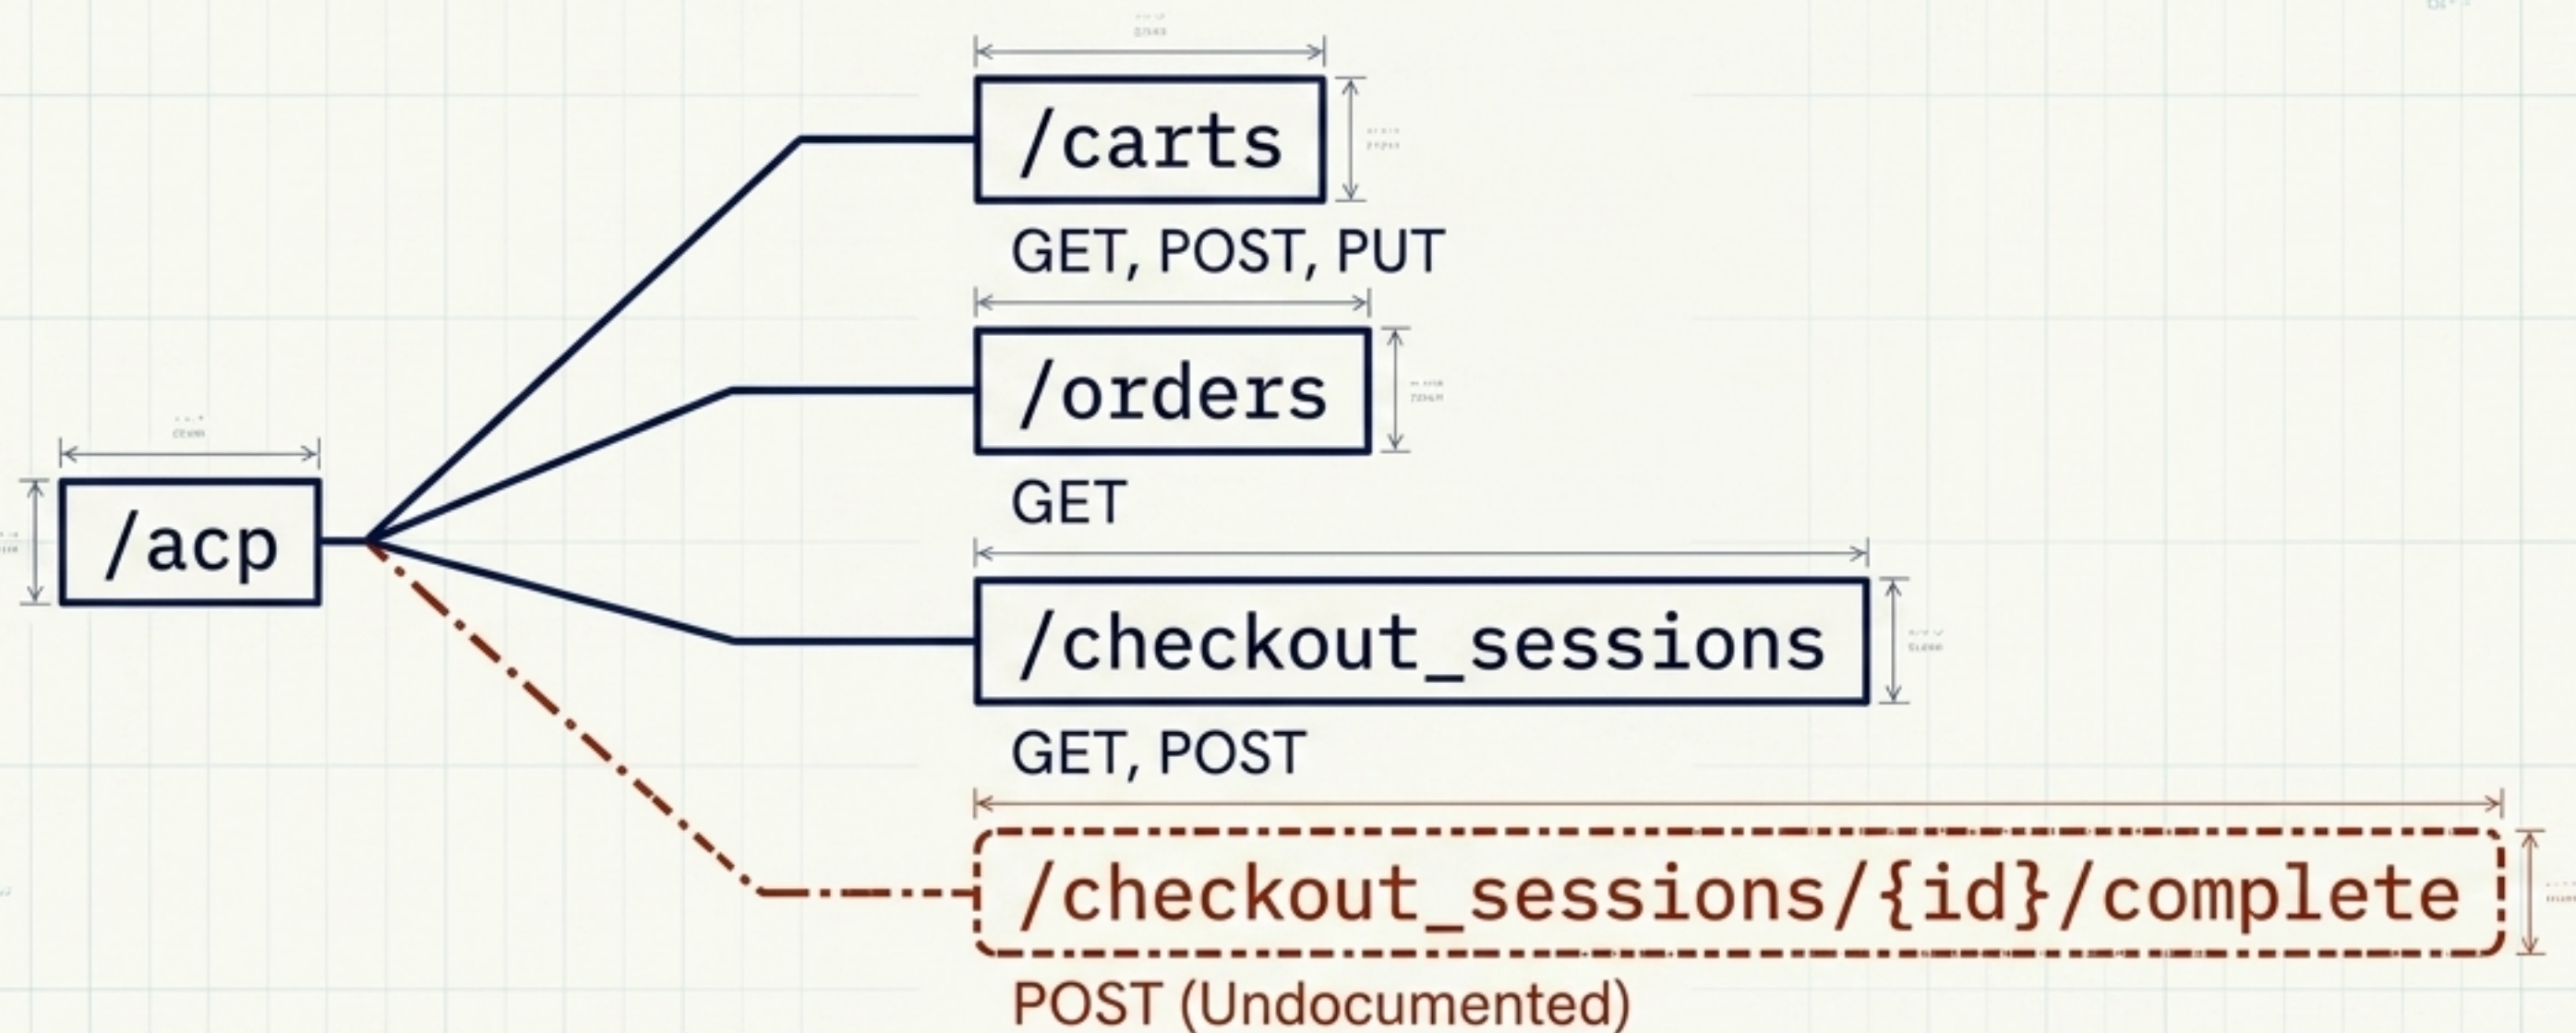

Agent

GET /.well-known/acp.json

The Protocol Envelope Response

<code>protocol.name</code>	acp	Confirms target identity
<code>protocol.version</code>	2026-01-30	Critical for later mutation headers
<code>api_base_url</code>	/acp	The root for all subsequent API calls
<code>capabilities.services</code>	['checkout', 'orders', 'carts']	Available resources

Fetching the contract reveals standard resources—and one hidden endpoint

The OpenAPI 3.0.0 specification declares standard REST capabilities and OAuth2 Bearer token auth. However, the crucial `/complete` sub-resource is absent from the spec and must be discovered via runtime exploration.

Aligning the request headers requires endpoint-specific logic.

Standard Operations (/carts, /checkout_sessions)	Mutation Operations (/checkout_sessions/{id}/complete)
Authentication: Authorization: Bearer <token>	Authentication: Authorization: Bearer <token>
Content Type: Content-Type: application/json	Content Type: Content-Type: application/json
Versioning: API-Version: 1.0	Versioning: API-Version: 2026-01-30 (Matches protocol version)
Traceability: Idempotency-Key (for safe retries)	Traceability: Idempotency-Key AND Request-Id (UUID for deduplication)

Semantic resolution turns human web pages into machine-actionable offers.

Offer

PriceSpecification

Offer IRI: <http://data.openlinksw.com/oplweb/offer/TestFileAccessOffer0ds-qa#this>
Price: USD \$9.99 (parsed as 999 cents)

⚠ Strict Enforcement: The #this hash fragment is absolute. Omitting it from the dereferenceable IRI yields a unit_amount: 0 error.

Carts are optional staging grounds; agents use direct checkout sessions.

Human-in-the-Loop

The Cart API (/carts)

- Designed for staging items.
- Presents UI for manual user review.
- Multi-step validation process.
- **Conclusion:** Wholly optional in ACP.

Autonomous Agent

The Session API (/checkout_sessions)

- The direct agentic path.
- Takes the resolved Offer IRI directly.
- Backend automatically creates a backing cart.
- **Conclusion:** Zero explicit /carts API calls required.

<http://data.openlinksw.com/oplnweb/offez/TestFile#access>

Architectural Conclusion: An agent can proceed directly from offer discovery to **POST /checkout_sessions**.

Generating the checkout session validates the semantic offer.

The Final Payload

POST /checkout_sessions requires three critical keys:

```
{  
  "line_items": "[Offer IRI]",  
  "currency": "'usd'",  
  "capabilities": "['payment']"  
}
```

State Transition

in_progress

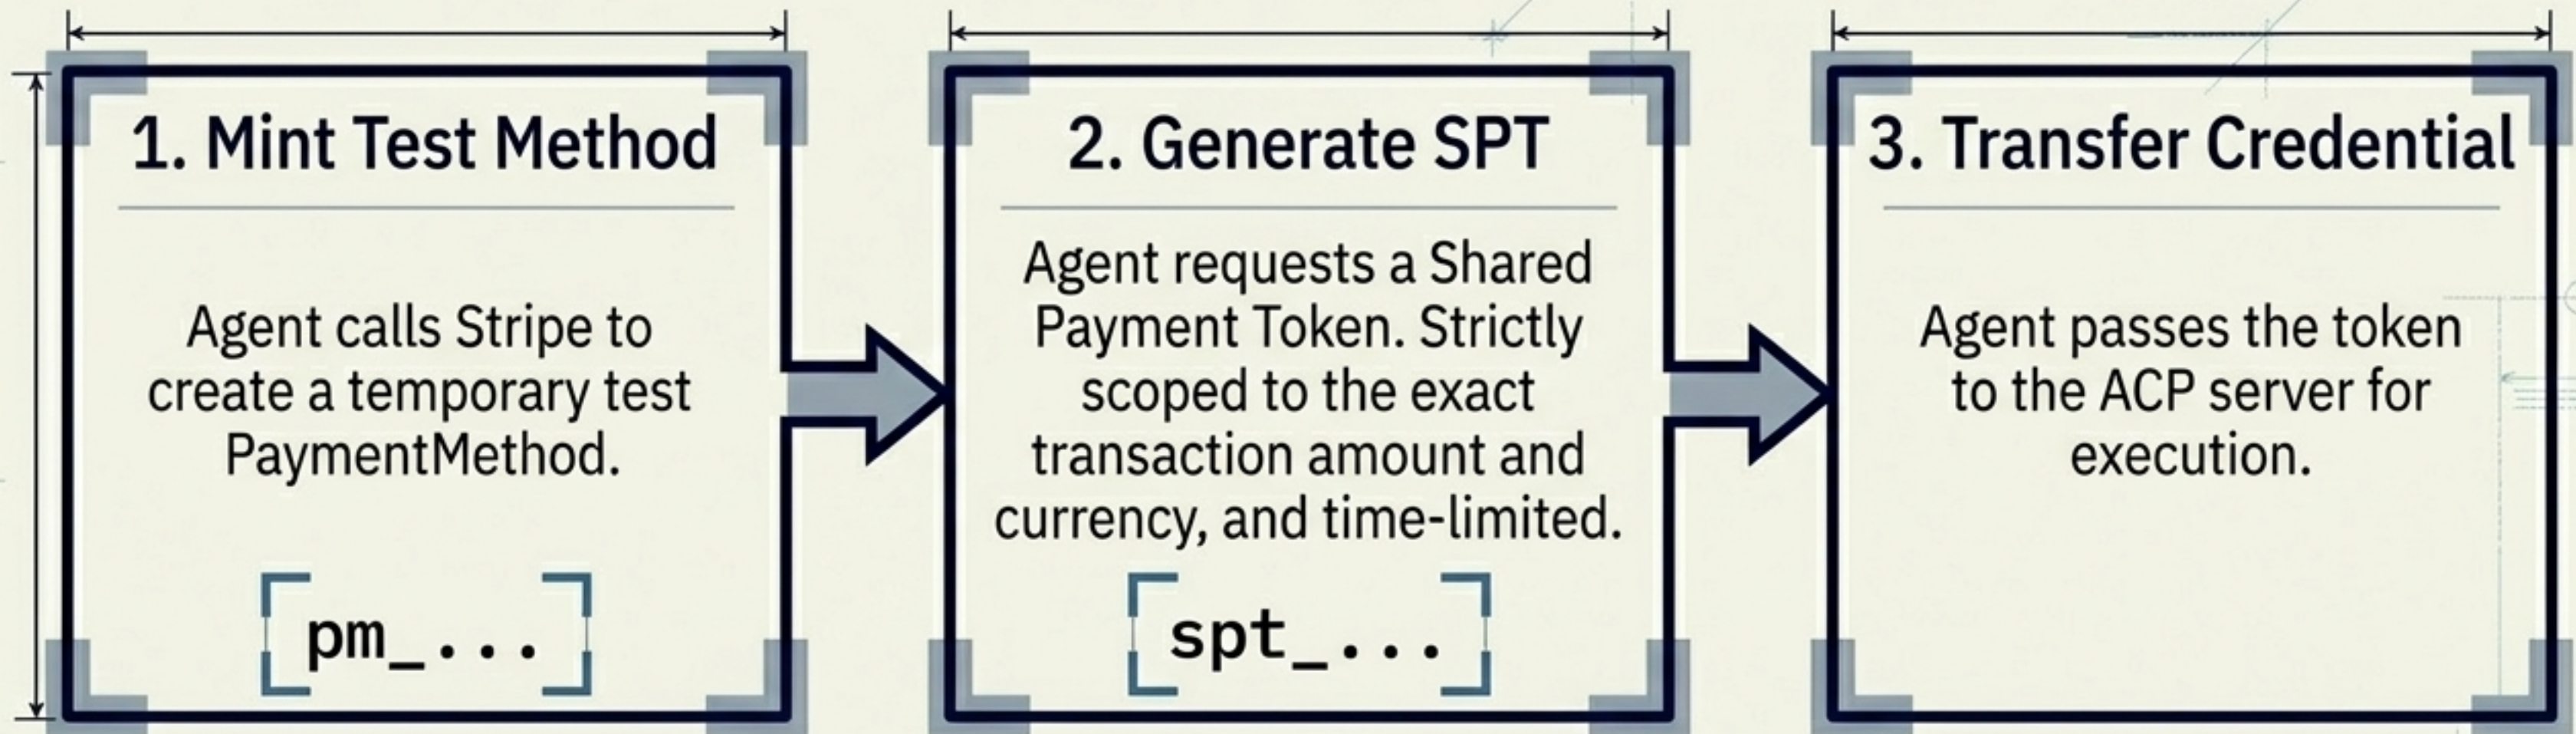

Session created, offer pending backend validation.

Backend validates IRI and fetches pricing.

ready_for_payment

Session locked and awaiting funds.

Tokenising payment protects card data via strict scoping.

Key Insight

Security Architecture: The merchant ACP server never receives raw card details—only the single-purpose SPT, mitigating security risks for autonomous clients.

Firing the sub-resource finalises the autonomous transaction.

POST Request

Target: `/acp/checkout_sessions/{id}/complete`

Headers:

- API-Version: 2026-01-30
- Request-Id: <UUID>

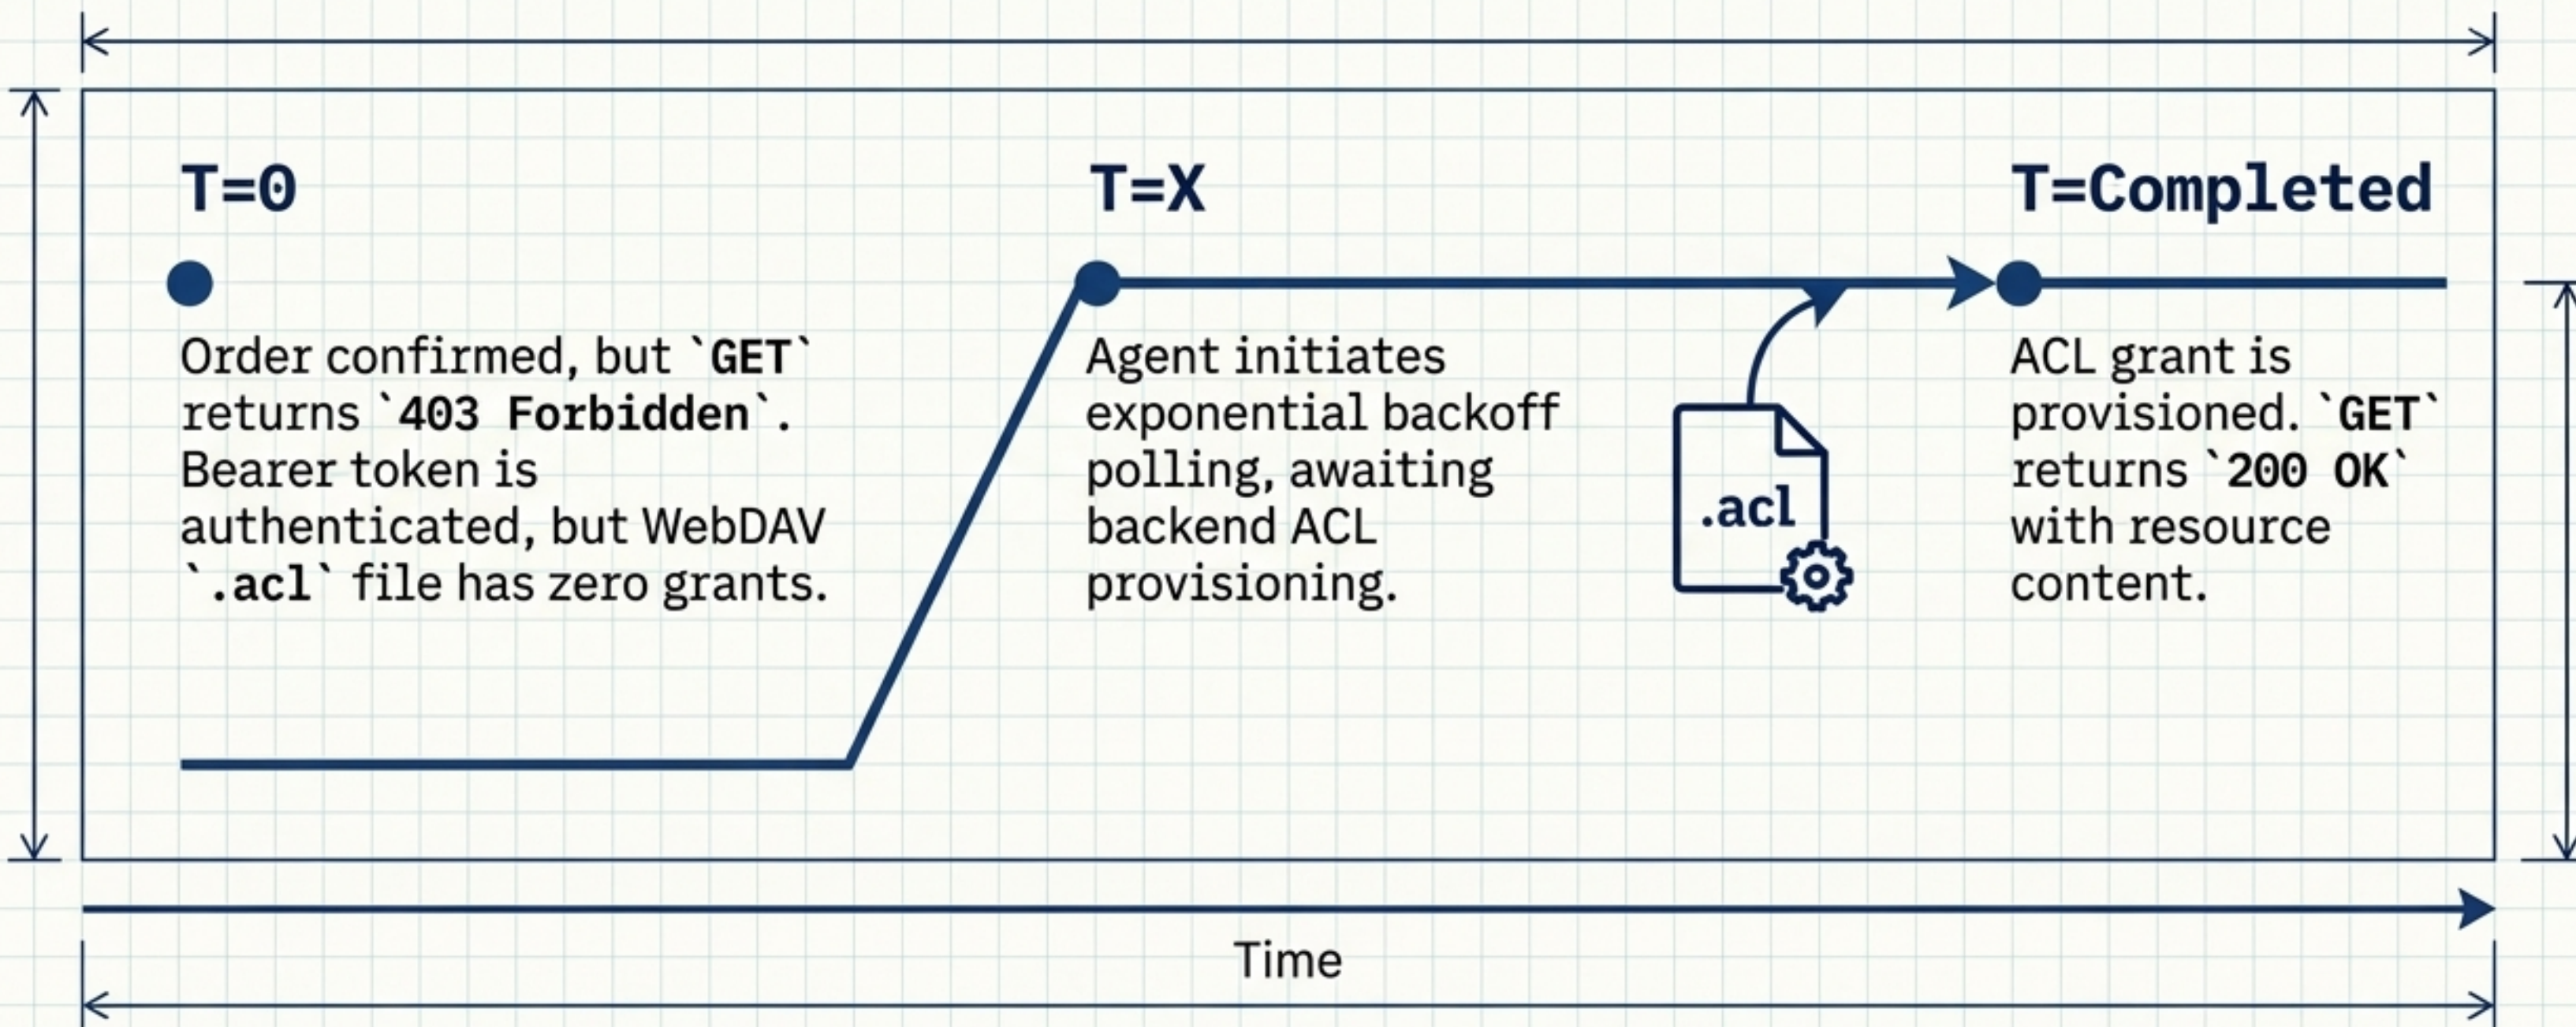

Payload:

```
{  
  "payment_data.handler_id": "card_tokenized",  
  "payment_data.instrument.credential.token": "spt_..."  
}
```

200 OK Response

- Status shifts to 'completed'.
- Embedded order object returns status: 'confirmed'.
- Yields target License IRI for Test File Access.

Agents must bridge the asynchronous access gap via polling

RES - 1 * 2 H, 5

Handling protocol edge cases: One-Time vs. Subscription logic.

One-Time Purchase 	Subscription Trigger 
Target Offer: TestFileAccess	Target Offer: XYZFileAccess
Order Status: confirmed	Order Status: confirmed
Messages Array: Empty	Messages Array: subscription_payment_required
Links Array: Empty	Links Array: rel='subscription_payment' (Contains Stripe Invoice URL)
Next Steps: Poll resource for WebDAV access.	Next Steps: Present URL for browser-based activation/3DS challenge.

The Agentic Catalog: 19 structured OPAL offers on ods-qa.

Band 1: **OPAL Modules (Data Twingler & Support Assistant)**

Tiers: Entry (Free) to Max (\$49.99)

Band 2: **API & Chat Services (BYOK)**

Tiers: API Access & Bring Your Own Key chat services.

Band 3: **File & Graph Access**

Includes TestFileAccess and DemoGraphAccess testing grounds.

Note: All catalog items exist as dereferenceable Linked Data resources terminating in the absolute **#this** fragment.

The Autonomous Receipt: A tokenised ledger of a human-free transaction.

The Analog Relic

The Agentic Receipt

Order Record: ord_... (status: confirmed)

Financials: USD \$9.99 (Stripe SPT processed)

Semantic Offer: TestFileAccessOffer0ds-qa#**this**

License Minted: .../TestFileAccessLicense0ds-qa#**this**

Resource Granted: <https://ods-qa.../DAV/data/TestFile.txt> (WebDAV ACL)

The **Agentic Commerce Protocol** enables **fully sovereign machine-to-machine** procurement through **semantic data, strict capability constraints, and tokenised trust.**
